Examples of damage in composites are multiple fiber-bridged matrix cracking in a unidirectional composite, multiple intralaminar cracking in a laminate, local delamination distributed in an interlaminar plane, and fiber/matrix interfacial slip associated with multiple matrix cracking.

The damage is modelled as a series of interacting matrix cracks in various forms: splitting, delamination and transverse

ply cracking. The extent of fatigue damage can be successfully predicted for a family of (90/0)_js and (90/+ 45/0)_s laminates.

Fatigue damage mechanics of composite materials. II: A ...

The damage in composite materials is completely different: a large number of microscopic events will develop very gradually over a large volume of the material. This is due to the heterogeneity of the material on a microscopic scale, as the matrix and reinforcement have different mechanical behaviors.

Abstract In this study, the continuum damage mechanics model for predicting the stiffness reduction of composite laminates including transverse cracks is formulated as a function of crack density. To formulate the model, first the damage variable in the direction normal to the fiber of a ply including transverse cracks is derived.

Impact damage tolerance in composite structures depends on two main phenomena: the loss of strength caused by the impact; and the detectability of the impact. This chapter discusses what impact damage looks like and how this damage develops to lead to the final fracture during compression after impact (CAI).

The advantages of composite materials include a high specific strength and stiffness, formability, and a comparative resistance to fatigue cracking and corrosion. However, not forsaking these advantages, composite materials are prone to a wide range of defects and damage that can significantly reduce the residual strength and stiffness of a structure or result in unfavorable load paths.
